

Amendments to the Claims:

This listing of claims replaces all prior versions, and listings, of claims in the application:

Listing of Claims:

1-16. (Cancelled)

17. (Previously Presented) A method of requesting access to a node of a wireless communications network, the method, comprising the steps of:

- a) determining information about a transmission path within the network;
- b) determining an identification code to differentially identify a requesting network component from other network components based on the determined transmission path information, wherein previously an association between identification codes and transmission path information has been established; and
- c) modulating, by the requesting network component, the determined identification code onto a signal to generate an access request signal from which transmission path information may be derived.

18. (Previously Presented) The method of claim 17, further comprising:

- d) analyzing an access control signal that is received in response to the access request signal and that includes access control information.

19. (Previously Presented) The method of claim 18, wherein the access control signal simultaneously includes access control information for a plurality of network components and wherein the access control information for each network component is associated in the access control signal with an individual identification code.

20. (Previously Presented) The method of claim 19, wherein the access control signal is subjected to an interference canceling step which includes subtracting

from the access control signal a compensation signal relating to access control information that is not associated with the identification code determined in step b).

21. (Previously Presented) The method of claim 17, wherein the access request signal including the identification code determined in step b) is transmitted repeatedly using transmit power ramping.

22. (Previously Presented) A method of controlling access to a node (BS) of a wireless communications network, the method comprising the steps of:

a) receiving an access request signal onto which an identification code has been modulated by a requesting network component, the identification codes differentially identifying the requesting network component from other network components;

b) analyzing the identification code to derive a transmit power level therefrom, wherein previously an association between identification codes and transmit power levels has been established;

c) transmitting an access control signal including access control information at the transmit power level derived in step b).

23. (Previously Presented) The method of claim 22, wherein step b) comprises analyzing the identification code with respect to transmission path information associated therewith, wherein the identification codes are associated via transmission path information with transmit power levels and wherein the transmit power level corresponding to a specific identification code is derived from the transmission path information corresponding to the specific identification code.

24. (Previously Presented) The method of claim 22, wherein the access control signal includes the identification code analyzed in step b).

25. (Previously Presented) The method of claim 22, wherein the access control signal simultaneously includes access control information for a plurality of

network components which are requesting access to the node and wherein the transmit power level for the access control signal is derived and adjusted individually for each network component which requests access.

26. (Previously Presented) The method of claim 17, wherein the identification code is selected out of a predefined set or range of identification codes.

27. (Previously Presented) A network component configured to request access to a node of a wireless communications network, said network component comprising:

a first determination unit for determining information about a transmission path within the network;

a database including data associating identification codes and transmission path information, wherein said identification codes differentially identify a requesting network component from other network components; and

a second determination unit for determining, in dependence on the determined transmission path information, an identification code to be included in an access request signal sent from the requesting network component from which transmission path information may be derived.

28. (Previously Presented) The network component of claim 27, further comprising:

a modulator for modulating the selected identification code onto a signal to generate the access request signal; and,

a transmitter for transmitting the access request signal.

29. (Previously Presented) A network component configured to control access to a node of a wireless communications system, the network component comprising:

a database including data associating identification codes from which transmit power information may be derived, wherein said identification codes differentially identify a requesting network component from other network components;

an analyzer for analyzing the identification code included within a received access request signal sent from the requesting network component, with respect to the transmit power information associated with the identification code; and,

a derivation unit for deriving from the transmit power information obtained by the analyzer a transmit power level for an access control signal.

30. (Previously Presented) The network component of claim 29, further comprising:

a receiver for receiving the access request signal onto which the identification code has been modulated; and,

a transmitter for transmitting the access control signal at the transmit power level derived by the derivation unit, wherein the access control signal includes access control information and, preferably, the identification code which has been modulated onto the received access request signal.
